

What is the purpose of line 86 to 88 ? Explain with examples

Lines 286–288 define a CSS class selector named `.hide` :

css

Copy code

```
.hide{
  display: none !important;
}
```

What’s the purpose?

If you add the class `hide` to any HTML element, that element will:

- 1. Disappear from the page
- 2. Not take up any space (it’s removed from the layout)

And `!important` means: “force this rule to win” even if other CSS tries to show the element.

Example 1: Hide a paragraph

html

Copy code

```
<p class="hide">You can’t see me.</p>
<p>I am visible.</p>
```

Result: the first `<p>` is completely hidden, the second shows normally.

Example 2: Show/Hide using a button (JavaScript)

This is a very common use of `.hide` .

html

Copy code

```
<button id="btn">Toggle</button>

<div id="box">
  Hello! I will be hidden/shown.
</div>

<style>
  .hide { display: none !important; }
</style>

<script>
  const btn = document.getElementById("btn");
  const box = document.getElementById("box");

  btn.addEventListener("click", () => {
    box.classList.toggle("hide");
  });
</script>
```

- Click button → `hide` class added → `display: none` → box disappears
- Click again → class removed → box appears

Why `!important` is used here?

Sometimes another CSS rule might be doing something like:

CSS Copy code

```
#box { display: block; }
```

Even then, `.hide { display: none !important; }` will still hide it, because `!important` makes it the strongest.

Quick comparison: `display: none` vs `visibility: hidden`

CSS Copy code

```
.a { display: none; }      /* gone + no space */
.b { visibility: hidden; } /* invisible but space remains */
```

So `.hide` is specifically for **completely removing an element from the page layout**.

If you want, paste your HTML part too—I can show exactly what it hides in your project.
